ABSTRACT

Gene modifications in animal models have been greatly facilitated through the application of targeted genome editing tools. The prokaryotic CRISPR/Cas9 type II genome editing system has recently been applied in cell lines and vertebrates. However, we still have very limited information about the efficiency of mutagenesis, germline transmission rates and off-target effects in genomes of model organisms. We now demonstrate that CRISPR/Cas9 mutagenesis in zebrafish is highly efficient, reaching up to 86.0%, and is heritable. The efficiency of the CRISPR/Cas9 system further facilitated the targeted knock-in of a protein tag provided by a donor oligonucleotide with knock-in efficiencies of 3.5-15.6%. Mutation rates at potential off-target sites are only 1.1-2.5%, demonstrating the specificity of the CRISPR/Cas9 system. The ease and efficiency of the CRISPR/Cas9 system with limited off-target effects make it a powerful genome engineering tool for in vitro studies.

INTRODUCTION

The induction of targeted mutations in zebrafish and other model organisms has only become possible through the use of genome editing tools, which induce mutations through DNA double-strand breaks and error-prone repair by non-homologous end joining. So far, genome editing has mostly been performed with zinc-finger nucleases (ZFNs) or transcription activator-like effector nucleases (TALENs). ZFNs can work very efficiently in zebrafish, but are expensive, difficult to design and function in a context-dependent manner. We now demonstrate that CRISPR/Cas9 mutagenesis in zebrafish is highly efficient, reaching up to 86.0%, and is heritable. The efficiency of the CRISPR/Cas9 system further facilitated the targeted knock-in of a protein tag provided by a donor oligonucleotide with knock-in efficiencies of 3.5-15.6%. Mutation rates at potential off-target sites are only 1.1-2.5%, demonstrating the specificity of the CRISPR/Cas9 system. The ease and efficiency of the CRISPR/Cas9 system with limited off-target effects make it a powerful genome engineering tool for in vitro studies.

RESULTS AND DISCUSSION

We designed four single-stranded gRNAs composed of the targeting sequence followed by the CRISPR sequence (supplementary material Fig. S1A) that guides the Cas9 nuclease to the desired genomic locus (Fig. 1A) (Jinek et al., 2012). gRNAs were designed to target the tardbp (bpt1), tardbp (bpt4) and C13H9orf72 (C9t2 and C9t3, targeting distinct sites) genes (Fig. 1B; supplementary material Fig. S1A,B). The gRNAs were obtained by in vitro transcription directly from synthesized oligonucleotides (C13H9orf72), PCR products (tardbp, tardbp, and C13H9orf72) as templates yielding comparable RNA quality. Since gRNA can be directly transcribed in vitro from synthetic oligonucleotides with similar efficiencies, laborious cloning procedures can be omitted (Fig. 1A). To demonstrate the efficiency of the CRISPR/Cas9 system in zebrafish we chose the tardbp and tardbp genomic loci, which we identified as suitable and accessible for ZFN in a previous study (Schmid et al., 2013). The gRNA/Cas9 system is derived from bacteria and archaea, where it is used as an innate immune strategy to inactivate foreign intruding nucleic acids (Wiedenheft et al., 2012). The CRISPR locus consists of short palindromic repeats and short interspersed sequences of foreign DNA. Upon transcription, they serve as guide RNA (gRNA) to identify foreign DNA and target it for inactivation by nuclease-mediated cleavage. The CRISPR/Cas9 type II system of Streptococcus pyogenes has been optimized and successfully used in vertebrate cells to edit genomes (Cho et al., 2013; Horvath and Barrangou, 2013; Jinek et al., 2013; Mali et al., 2013; Shen et al., 2013; Wang et al., 2013). Recently, it has been further demonstrated to efficiently generate insertions and deletions due to incorrect repair by non-homologous end joining of induced double-strand breaks in zebrafish (Chang et al., 2013; Hwang et al., 2013a; Hwang et al., 2013b; Jao et al., 2013). We now demonstrate that the CRISPR/Cas9 system is highly efficient and specific in generating heritable mutations and knock-in (KI) alleles in zebrafish with negligible off-target effects.
Fig. 1. Overview of the CRISPR/Cas9 system and mutation analysis of injected P0 founder embryos. (A) Guide oligonucleotides containing a T7 RNA polymerase binding site were annealed with T7 primer (blue). gRNA and Cas9 mRNA were co-injected into zebrafish embryos. The gRNA detects the endogenous genomic target site and can base pair via its target binding site, recruiting Cas9 protein (green) to induce a double-strand break at the target site (indicated by scissors) close to the protospacer adjacent motif (PAM). (B) PCR and restriction enzyme analysis of individual P0 embryos injected with bpt1, bpt4, C9t2 or C9t3 gRNA and Cas9 as indicated. PCR products are shown undigested (PCR) or after digestion with the appropriate restriction enzyme as indicated. Lanes 1-4 show un.injected siblings, whereas lanes 5-8 represent individual P0 founder embryos injected with the indicated gRNA/Cas9 mRNA. Red arrows indicate loss of restriction sites due to genomic mutations.

Encouraged by the efficiency and specificity of the CRISPR/Cas9 system we speculated that it might be suitable to facilitate a targeted KI approach in zebrafish. We designed a donor oligonucleotide containing an HA tag flanked by a 41 nt left and a 49 nt right homology arm to introduce the HA tag of the donor oligonucleotide (hereafter referred to as C9t3 KI injected) and screened 20 embryos for successful KI by PCR (supplementary material Fig. S3B). Nine out of 20 injected P0 embryos (45%) were positive by PCR screening for successful KI (Fig. 3B). We next raised the injected embryos and prescreened fin biopsies of adult fish for successful KI (supplementary material Fig. S4A). From four positively prescreened founder fish we recovered two alleles containing the HA tag (supplementary material Fig. S4B). However, both lines had mutations in addition to integration of the HA tag (supplementary material Fig. S4A).
A high rate of mutagenesis (50-76%) of the injected embryos was observed. Additionally, the embryos showed on average a KI rate of 3.5%, of which about half (1.7%) showed correct KI without additional mutations (Fig. 3C, D; supplementary material Fig. S5). CRISPR/Cas9 is therefore not only efficient to generate mutations in zebrafish but also suitable for KI strategies. However, the inserted HA tag at the C9t3 locus was not detectable by western blot analysis or immunohistochemistry, most likely owing to low expression of the C13H9orf72 protein. We therefore used a similar strategy at the bpt1 site, which is actively transcribed and translated (Schmid et al., 2013). We co-injected the bpt1 gRNA, Cas9 mRNA and a donor oligonucleotide with a 33 nt left homology arm, two HA tags to improve detection sensitivity, and a 33 nt right homology arm (hereafter referred to as bpt1 KI injected) (Fig. 4A). Fourteen of the 20 (70%) injected embryos analyzed were positive by PCR analysis for the HA tag, indicating successful integration (Fig. 4B).

To determine the KI efficiency at the bpt1 locus, we subjected ten bpt1 KI injected embryos to NGS analysis. The efficiency to induce mutations varied between embryos (61-98%) and was on average 86.0% (Fig. 4C; supplementary material Fig. S6). The average HA tag integration rate was 15.6%, but only 3.5% had a correct KI without any additional mutations (Fig. 4F). The high KI efficiency at the bpt1 locus is most likely due to the highly efficient bpt1 gRNA (reaching up to 98% mutagenesis efficiency), increasing the chances of an early double-strand break and donor DNA integration. Consistent with the high mutagenesis rates in the injected founder embryos we detected reduced levels of Tardbp protein by western blot upon bpt1 KI injection (Fig. 4D). Using a sensitive anti-HA tag antibody we could further detect the Tardbp-HA fusion protein at the expected molecular weight of 44 kDa by western blot in injected founder embryos (Fig. 4D). Importantly, the nuclear localization of Tardbp (Shankaran et al., 2008) was recapitulated by immunohistochemistry with the HA-specific antibody (Fig. 4E).

In conclusion, we have adapted the protocol to efficiently synthesize gRNA without any cloning and show efficient mutagenesis, KI and germline transmission, comparable to TALEN and ZFN approaches (Bedell et al., 2012; Blackburn et al., 2013; Chang et al., 2013; Hwang et al., 2013b). Most importantly, we provide evidence of limited off-target effects and efficient KI, especially upon preselection of founder fish. In contrast to ZFN or TALEN, the design and generation of CRISPR/Cas9 RNAs is much cheaper and less time consuming, making it an excellent genome editing tool, and not only in zebrafish. This system further opens new avenues for the analysis of gene function in vivo and for the generation of new disease models in vertebrates.
MATERIALS AND METHODS

Zebrafish

Zebrafish (Danio rerio) embryos were kept at 28.5°C and were staged according to Kimmel et al. (Kimmel et al., 1995). The wild-type line AB was used. All experiments were performed in accordance with animal protection standards of the Ludwig-Maximilians University Munich and were approved by the government of Upper Bavaria (Regierung von Oberbayern, Munich, Germany).

Guide oligonucleotide

The gRNA antisense oligonucleotide sequence (5′-3′) was: AAAGCACCGACTGGTGCACACTTTTTCAAGTTGATAACGGACTAGCCTTATTTTAACTTGCTATTTCTAGCTCTAAAA CNNNNNNNNNNNNNNNNNNNNCT- ATAGTGAGTCGTATTA CGC, with the T7 site shown in bold, N 20 indicating the targeting sequence, and the gRNA scaffold adopted from Mali et al. (Mali et al., 2013) shown in italics (see Fig. 1A; supplementary material Fig. S1A).

The targeting sequences (N 20) used for the respective gRNA (in parenthesis) were:
- **tardbp** targeting oligo 1 (bpt1), CCCATGTTGCTT-CGGCTGCC;
- **tardbpl** targeting oligo 4 (bplt4), AACTACTCTGAAGTGCTG- TGCC;
- **C13H9orf72** targeting oligo 2 (C9t2), TCACTGAGCAGCAGCA- ACCC; and
- **C13H9orf72** targeting oligo 3 (C9t3), ATCATGTCTTCA- GCCTGTCC.

For direct in vitro transcription, the gRNA antisense oligonucleotide was annealed to the T7 primer (TAATACGACTCACTATAG; 5 minutes at 95°C, then cooled at room temperature for 5 hours) and in vitro transcribed using the Ambion MEGAshortscript-T7 kit.

For microinjection and knock in

The PCR product gel-purified and subcloned into pCR8/GW/TOPO/TA (Invitrogen). The insert was excised using DraI and ApaI (NEB). The excised insert and PCR product were in vitro transcribed using the MEGAscript-T7 kit.

**Cas9**

Nuclear localization sequences on both ends and one C-terminal HA tag were added to wild-type Cas9 from Streptococcus pyogenes (Addgene, 39312) by PCR (supplementary material Fig. S1C) using primer 1 (ATGGCCCAAAAGAAGAAGCGCAAGGTAGGTGGAGGTGGAGGAGGAGATATAAGATACCTATAGGGCTTAG) and primer 2 (TCAAGCGTTTGAGTCGTATGGGTAACCTCCTCCTCCTTACCTTACGCTTCTTCTTGGAGCACCTCCTCCTCCTCCGACCTCCTCCTACCGTACCT).

The PCR product was subcloned into a pCR8/GW/TOPO vector (Invitrogen) and further recombined into pcS2+/GW using LR Clonase II (Invitrogen). After linearization with ApaI (NEB), Cas9 was in vitro transcribed using the SP6 mMESSAGE mMACHINE kit (Ambion).

**Microinjection and knock in**

gRNAs were microinjected (Femptojet, Eppendorf) at a final concentration of 2.4 μg/μl together with 0.5 μg/μl Cas9 mRNA into fertilized one-cell stage embryos. For KI, 100 nM donor oligonucleotide was co-injected. Uninjected siblings were used as controls. Oligonucleotides were (HA tag sequence in bold): donor oligonucleotide for C9t3 (120 nt), CTTC-TGCTTTTGAGTCGTATGGGTAACCTCCTCCTCCTTACCTTACGCTTCTTCTTGGAGCACCTCCTCCTCCTCCGACCTCCTCCTACCGTACCT.

Fig. 3. HA tag knock-in at the C9t3 locus.

(A) The KI strategy at the C9t3 locus. (B) PCR analysis of individual KI injected embryos. Red arrows indicate successful donor oligonucleotide genomic integration.

(C) Average frequencies among ten embryos of C9t3 KI NGS reads mapped to wild-type (wt, left) and KI (right) sequence. In both panels 0 indicates correctly mapped reads without indels (left, 0=wt, no indels; right, 0=correct KI, no indels). Negative values are deletions and positive values are insertions.

(D) Summary of NGS data for the C9t3 KI analysis.

NGS of C9t3 KI injected embryos

- reads total: 543088
- average % reads with mutations: 64.1%
- average % reads with KI: 3.5%
- average % reads with correct KI: 1.7%
PCR analysis
DNA of 1 dpf embryos was used as a template for PCR with the following primers: C13H9orf72-for (genotyping C9t2 and C9t3), GCAACTCTTTTGTCACCCACT; C13H9orf72-rev (genotyping C9t2 and C9t3), ATCAACCTCCTCTGCACAC; tardbp-for (genotyping bpt1), GAAGAAATTTCCAACTTCTTTC; tardbp-rev (genotyping bpt1), ACTTACCAAAACACGCTAGG; tardbpl-for (genotyping bplt4), GCCTAAGCACAATAATAGTAGG; tardbpl-rev (genotyping bplt4), CTCTACTACCACTCTGC; C9t3-HA-tag-for (genotyping HA KI C9t3), CCCTATCATGTACCTATTACG; 2x-HA-tag-for (genotyping HA KI bpt1), CTCTACTACCACTCTGC; C9t3-HA-tag-rev (genotyping HA KI C9t3), ACGCTAGG; and tardbp-rev (genotyping HA KI in bpt1), ACTTACCAAAACACGCTAGG.

For RFLP analysis, half of the PCR product was digested with the following enzymes (NEB): tardbp (bpt1), CspCI; tardbpl (bplt4), Hpy188I; C13H9orf72 (C9t2), Ddel; C13H9orf72 (C9t3), BblI.

Next generation sequencing
Putative off-target sites of the C9t3 gRNA were identified by BLAST search of the 13 nt 5’ of the PAM motif containing an NGG motif (previously described to be crucial for binding) (Cong et al., 2013; Jinek et al., 2012).
using Ensembl Genome assembly Zv9 (GCA_000002035.2). The DNA of ten individual embryos injected with Cas9 and C9R3 gRNA was pooled and analyzed for C9R3 gRNA target effects and off-target effects. From this pool we PCR amplified the C9R3 locus and the four potential off-target sites (supplementary material Fig. S3). Ten individual embryos injected with C9R3 gRNA, Cas9 mRNA and the donor oligonucleotide were PCR amplified and analyzed individually for KI efficiency (supplementary material Fig. S5). Adapter ligation, sequencing and tag sorting were performed by GATC Biotech (Germany). KI analysis at the bpt1 locus was performed (supplementary material Fig. S6). The length of the expected PCR products varied between 184 bp and 417 bp. We sequenced on a MiSeq platform (Illumina) in paired-end mode of appropriate length (140 bp or 250 bp). Templates of the C9R3 gRNA target sites and potential off-target sites were used as reference sequences for determination of the off-target lesions (supplementary material Fig. S3). Templates of bpt1 and C9R3 with and without inserted HA tags and the C9t3-associated off-target sites were used as reference sequences for determination of KI efficiency (supplementary material Figs S5, S6). Reference-guided sequence assemblies were performed with Novoalign (v3, Novocraft). The frequency of insertions and deletions around the best-matching reference sequence was derived from the CIGAR code of the sequence alignments (Java and R scripts for statistical evaluation are available upon request). Primers used for barcode labeling are also available upon request.

Western blot analysis and immunohistochemistry

Western blotting (WB) and immunohistochemistry (IHC) were performed as previously described (Schmid et al., 2013). Primary antibodies used: Tardbp 4A12-111 (Tardbp epitope: TSTSGTSSSRDQAQTY), WB 1:1000; IHC 1:200.
